

At the beginning of Unit 2, you read about a chemical reaction that is used to weld railroad tracks together. This is just one of the many reactions that are involved in the processes required to make the products you use in your daily life. Chemical reactions are also involved in cleaning up the problems that result from these processes.

Thermite Reactions

Now that you have learned more about chemical reactions, you can re-examine thermite reactions. When this type of reaction is used to weld railroad tracks, the reactants, aluminum and iron oxide are powdered and thoroughly mixed. The reaction is a single displacement reaction in which aluminum displaces iron according to the following balanced chemical equation:

Once the reaction begins, it releases enough energy to melt the iron.

In **Figure 4.13**, an aluminum wrench is hitting rusty iron, causing a small-scale thermite reaction that produces sparks. In industrial settings or workshops, the grinding or cutting of iron or steel can produce powdered iron oxides. Care must be taken in such areas to avoid an unexpected thermite reaction when using aluminum objects.

In addition to iron oxide, other metals can be used in thermite reactions. For example, a thermite reaction involving copper(II) oxide can be used to produce pure copper according to the following chemical equation:

This reaction is often used to produce pure copper for welding electrical conductors. The copper(II) oxide is held in a heat-resistant reaction chamber. The thermite reaction heats the copper enough to melt it. The liquid copper is then allowed to flow into a mold that surrounds the ends of the conductors. When the copper cools into a solid, it forms a weld that allows an electric current to flow between the conductors.

Figure 4.13 The friction from the impact of an aluminum wrench with rusty iron generated enough heat to initiate a small thermite reaction, as shown by the bright sparks flying away from the point of impact.

Analyze The thermite reaction shown here occurs in the solid state. How is this different from the other single displacement reactions you have studied?

Figure 4.14 This plant processes seawater to extract magnesium.

Magnesium Mining from Seawater

Many metals, such as copper, zinc, and gold, are extracted from solid ores. Although magnesium is abundant in Earth's crust, it is extracted from seawater, not rocks. As a result, plants that produce magnesium, such as the one shown in **Figure 4.14**, are usually located on the coast. Magnesium ions are the second most abundant cations found in seawater, with only sodium ions in greater abundance. The process of producing metallic magnesium requires several chemical reactions.

Steps in the Process of Magnesium Mining

Figure 4.15 shows the main steps in extracting magnesium from seawater. The steps in the flowchart match the reactions described below.

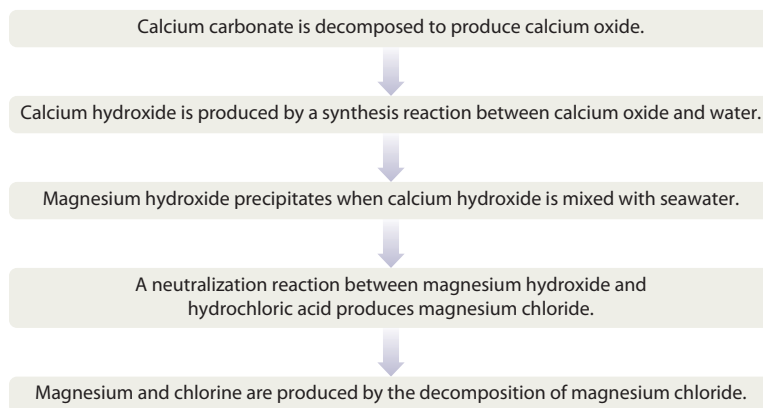

Figure 4.15 Use this flowchart to help you understand the sequence of chemical reactions used in the extraction of magnesium from seawater.

Decomposition of Calcium Carbonate

First, calcium carbonate from seashells is decomposed to produce calcium oxide. Recall, from Chapter 3, that carbon dioxide is a product when a metal carbonate decomposes. The chemical equation is

Synthesis of Calcium Hydroxide

The calcium oxide undergoes a synthesis reaction to form calcium hydroxide:

Double Displacement between Calcium Hydroxide and Magnesium Compounds

The calcium hydroxide reacts with the magnesium ions in seawater in a double displacement reaction. The magnesium ions are separated from the other ions in seawater, such as sodium, chloride, and bromide ions, as the precipitate magnesium hydroxide:

Neutralization of Magnesium Hydroxide

The solid magnesium hydroxide is filtered out and undergoes neutralization with hydrochloric acid:

Decomposition of Magnesium Chloride

The magnesium chloride is dried, melted, and then decomposed through electrolysis to form magnesium metal:

Industrial Uses of Magnesium

The main industrial use for magnesium is in the manufacturing of aluminum-magnesium alloys. An *alloy* is a mixture of two or more metals. Because magnesium is a less dense metal than aluminum, their alloys are lighter in weight than pure aluminum. In addition, the alloys are stronger and more resistant to corrosion than pure aluminum. Beverage cans are often made of aluminum to which a small amount of magnesium has been added, making the metal stronger and easier to shape. Magnesium is also commonly used in electronic devices because of its light weight and its electrical properties. The kayak shown in **Figure 4.16** is made, in part, of an alloy of aluminum and magnesium.

Figure 4.16 The frame of this kayak is constructed using tubing that is made from an alloy of aluminum and magnesium.

Infer What properties of aluminum-magnesium tubing make it suitable for constructing a kayak?

Learning Check

- Describe the displacement that occurs in a thermite reaction involving iron oxide.
- What product makes a thermite reaction useful for welding?
- Explain how a thermite reaction can be used to produce pure copper.
- How are seashells used to help extract magnesium from seawater?
- During the extraction of magnesium from seawater, why is a precipitate of magnesium formed, if it is converted into soluble magnesium chloride in the next step?
- Refer to **Figure 4.15**. What is an advantage of the production of chlorine in the final step of extracting magnesium from seawater?

Extracting Metals from Ores

Gold and copper are important metals for Canada's economy. Several different methods are used for extracting these metals. Each method combines physical processes, such as grinding and filtering, and chemical processes to obtain the desired product.

Copper Smelting

A smelter is a facility that uses heat to extract metal from ore. **Figure 4.17** shows a smelter that is used to refine copper at the Kidd Creek copper and zinc mine in Timmins, Ontario. An important part of the design of this type of smelter is the different heights of the furnaces. Molten products flow from one furnace continuously into the next furnace because of the height difference, reducing the need for large buckets and transfer equipment.

Figure 4.17 These furnaces produce increasingly pure copper through a series of reactions.

Identify how the construction of the smelter allows gravity to move the material from one furnace to the next.

Smelting Furnace

The smelting furnace is the first stage of copper production. An impure copper sulfide **matte**, $\text{Cu}_2\text{S}(\ell)$, forms. Oxygen is used to separate the iron from the copper in the mineral chalcopyrite, $\text{CuFeS}_2(\text{s})$, ore according to this overall reaction:

The iron(II) oxide is reacted with sand and limestone to convert it into a low density compound called *slag* which floats to the top of the molten mixture. The copper matte is more dense and sinks to the bottom.

The sulfur dioxide gas that is produced in these reactions and in later steps of the process is collected and sent to a plant that produces sulfuric acid. This prevents the release of large amounts of pollutants that contribute to the formation of acid precipitation.

Slag-Cleaning Furnace

The products of the smelting furnace move to the slag-cleaning furnace, where they separate due to differences in density. The matte flows into the converting furnace, while the undesired material, called *slag*, is sent to storage.

Converting Furnace and Anode Furnace

In the next step, matte is purified further, to about 99 percent, in the converting furnace through further displacement reactions. Air is blown through the molten mixture and oxygen in the air reacts with the copper matte in a two step reaction. First, some copper(I) sulfide is converted to copper(I) oxide. The copper(I) oxide then reacts with more copper(I) sulfide to form metallic copper and sulfur dioxide.

matte an impure copper(I) sulfide mixture that is formed by smelting the sulfide ore

Suggested Investigation

Inquiry Investigation 4-E,
From Copper to Copper

As in the earlier furnaces, the sulfur dioxide gas is collected, so it can be sent to a plant that produces sulfuric acid. The small furnaces make it easier to recover the gases and provide a steady stream of sulfur dioxide to the acid plant. Meanwhile, the copper undergoes a final purification step in the anode furnace.

Because copper is an excellent conductor of electricity, a major use of copper is in electrical wiring. Copper is also melted with other metals to make alloys. For example, bronze is mainly an alloy of copper and tin, and brass is mainly an alloy of copper and zinc.

Gold and Cyanide Leaching

Gold is a relatively non-reactive metal. As a result, it can be found in nature in its uncombined form. As shown in **Figure 4.18**, however, most gold is mixed into the rock that surrounds it and must be separated. The most cost-effective method for removing the gold involves treating the crushed rock with a sodium cyanide solution to dissolve the gold.

Go to **scienceontario**
to find out more

Figure 4.18 Much of the rock mined as gold ore contains particles of gold that are too tiny to be seen without a microscope. Some rocks, however, such as the one shown here, contain visible particles of gold.

Leaching is the process of converting a metal to a soluble form to extract the metal. A commonly used process for the extraction of gold from ore is to react it with a solution of sodium cyanide, $\text{NaCN}(\text{aq})$, to form sodium dicyanoaurate(I), $\text{Na}[\text{Au}(\text{CN})_2](\text{aq})$, and sodium hydroxide. The overall reaction for leaching gold is

The gold is recovered from the solution through displacement by zinc, according to the following equation:

The cyanide solution can be recycled and used again to convert gold to a soluble form in an aqueous solution.

In industry, the most important use of gold is in the manufacture of electronics components. Gold is an excellent conductor of electricity and is resistant to corrosion, so it is used in small amounts in electronic devices, including cell phones and computers. Gold is also an ingredient in some medications. In addition, it is used to fill cavities in teeth and to make crowns to cover and protect teeth. Gold is highly suited to such uses because it does not corrode, it does not trigger allergic reactions, and it is easy to shape into the desired form. Gold coins have been used for many centuries as currency. Other uses of gold include the production of jewelry, watches, and art objects.

leaching a process that is used to extract a metal by dissolving the metal in an aqueous solution

Waste and Spill Treatment

Because of the potentially harmful effects of the chemicals that are used and formed during metal production, steps are taken to reduce emissions and to respond to spills.

Sulfur Dioxide Waste

Some industries, such as coal-burning power plants, use scrubbers to remove sulfur dioxide, $\text{SO}_2(\text{g})$, from exhaust gases to prevent its release into the atmosphere. If sulfur dioxide is released into the atmosphere, it can eventually become sulfuric acid in rain and snow.

Because many metals, such as copper, are found as sulfide ores, large amounts of sulfur dioxide are commonly formed during metal extraction and purification. Sulfur dioxide can be converted into sulfuric acid, which is either used in some of the purification steps or sold. You may recognize the synthesis reactions that are involved in forming sulfuric acid from Chapter 3:

Cyanide Spills

Cyanide leaching allows gold to be extracted from ores that would have too low a gold content to be profitable. Unfortunately, cyanide is deadly in very small amounts if ingested. A cyanide spill may occur if the wall of a holding pond breaks or if a storm produces a large amount of rain and causes the holding pond to overflow. Two methods are commonly used to treat a cyanide spill.

Use of Sodium Hypochlorite

The first method is a two-reaction process. In the first reaction, sodium hypochlorite, the active ingredient in many chlorine bleaches, is added to the cyanide solution:

Sodium cyanate, $\text{NaCNO}(\text{aq})$, much less toxic than sodium cyanide. However, the second reaction entirely eliminates any toxicity. Additional sodium hypochlorite is used to convert the sodium cyanate into non-toxic compounds:

Use of Iron(II) Sulfate

The second method involves adding iron(II) sulfate, which binds the toxic and soluble cyanide ions into non-hazardous, complex iron(II) cyanide ions. The iron(II) cyanide ions form precipitates with many metal ions, such as zinc and iron, as shown in

Figure 4.19.

First, a double displacement reaction occurs:

Next, a synthesis reaction forms the polyatomic ion, iron(II) cyanide ions:

Finally, double displacement reactions, such as the reaction below, cause the iron(II) cyanide ions to form precipitates with other metal ions that are present.

Figure 4.19 The precipitate that is formed in the reaction between sodium iron(II) cyanide and iron(III) chloride is a pigment known as Prussian blue. This pigment is used in blueprints and paints.

Infer Why is forming a precipitate helpful when cleaning up a cyanide spill?

Section Summary

- A thermite reaction, used to weld railroad tracks, is a single displacement reaction between aluminum and iron oxide.
- Extracting magnesium from seawater involves several chemical reactions, including a double displacement reaction that forms a magnesium hydroxide precipitate and a neutralization reaction that forms soluble magnesium chloride.
- One method for refining copper involves several reactions in which oxygen displaces sulfur in an ore.
- After gold is leached from crushed rock using cyanide, it is recovered from the solution through displacement by zinc.
- The sulfur dioxide gas that is produced during metal refining can be collected and converted into sulfuric acid, through synthesis reactions, to prevent its release into the atmosphere.
- Sodium hypochlorite and iron(II) sulfate can be used to treat a toxic cyanide spill, making the spill less toxic.

Review Questions

- T/I** In a thermite reaction, why are the aluminum and metal oxide in powdered form rather than large pieces?
- A** What are some benefits of using reactants in the solid state in a thermite reaction, rather than the states of the reactants in most other single displacement reactions you have studied?
- C** Create a Venn diagram to compare the extraction of magnesium from seawater with the extraction of gold and copper from their sources.
- K/U** What type of reaction provides the calcium oxide that is used to extract magnesium from seawater?
- C** Create a graphic organizer to summarize the reactions involved in the extraction of magnesium from seawater.
- K/U** In the extraction of magnesium from seawater, what is the key process that is used to separate magnesium ions from all the other ions that are dissolved in seawater?
- K/U** What is the purpose of the neutralization step in the extraction of magnesium from seawater?
- A** A power plant built on the coast of an ocean can be designed to use the motion of water between high and low tides to generate electricity.
 - What step of magnesium extraction might benefit from construction of such a power plant? Explain your reasoning.
 - Give the balanced chemical equation that is associated with the step you identified.
- K/U** What chemical compounds are produced in the smelting furnace during copper production?
- C** Compare matte with slag in copper refining.
- T/I** Why is zinc able to displace gold that was leached from an ore?
- A** What process in the extraction of gold is modelled in this photograph?

- Instead of releasing the sulfur dioxide gas produced during metal refining into the environment, a company may convert it into sulfuric acid.
 - What is an environmental benefit of this process?
 - What is an economic benefit of this process for the company?
 - Give the balanced chemical equations that describe the production of sulfur dioxide gas during the smelting of copper.
- K/U** Name two chemicals that are used to clean up a cyanide spill.
- A** During a clean-up of a contaminated site, a barrel containing a cyanide solution is discovered. In terms of the final products formed, which treatment of the solution would be preferred? Explain your reasoning.
- K/U** Why are hexacyanoferrate(II) ions important in the treatment of a cyanide spill with iron(II) sulfate?
